## **OMNIPOWER IMPLEMENTATION**

# 1.1 Parse Kamstrup OmniPower wm-bus telegrams

platform Python 3.5.10 on Linux, OS X

synopsis Implements parsing functionality for C1 telegrams and log handling for data series

author Janus Bo Andersen

date 14 October 2020

#### 1.1.1 Overview

- This module implements parsing for the Kamstrup OmniPower meter, single-phase.
- The meter sends wm-bus C1 (compact one-way) telegrams.
- Telegrams on wm-bus are little-endian, i.e. LSB first.
- The meter sends 1 long and 7 short telegrams, and then repeats.
- Long telegrams include data record headers (DRH) and data, that is DIF/VIF codes + data.
- Short telegrams only include data.

### 1.1.2 Telegram fields

In a telegram C1 telegram, the data fields are:

#	Byte#	Byte	s M-bus	Description	Expected value (little-endian)
			field		
0	0	1	L	Telegram length	0x27 (39 bytes, short frame), or
					0x2D (45 bytes, long frame)
1	1	1	C	Control field (type and purpose of mes-	0x44 (SND_NR)
				sage)	
2	2-3	2	M	Manufacturer ID (official ID code)	0x2D2C (KAM)
3	4-7	4	A	Address (meter serial number)	0x57686632 (big-
					endian:32666857)
4	8	1	Ver.	Version number of the wm-bus firmware	0x30
5	9	1	Medium	Type / medium of meter	0x02 (Electricity)
6	10	1	CI	Control Information	0x8D (Extended Link Layer 2)
7	11	1	CC	Communication Control	0x20 (Slow response sync.)
8	12	1	ACC	Access field	Varies
9	13-16	4	AES	AES counter	Varies, used for decryption
			CTR		
10	17-39	23	Data	Contains AES-encrypted data frame,	Encrypted data
	17-45	29		varying for short and long frames	
11		2	CRC16	CRC16 check	

The fields 0-9 of the telegram can be unpacked using the little-endian format < BBHIBBBBB, where

- < marks little-endian,
- *B* is an unsigned 1 byte (char),
- *H* is an unsigned 2 byte (short),
- *I* is an unsigned 4 byte (int)

### 1.1.3 Telegram examples

Encrypted short telegrams:

L	С	М	Α	Ver	Med	CI	CC	ACC	AES	Encrypted payload	CRC
									CTR		16
27	44	2D	5768	30	02	8D	20	2E	2187	D3A4F149 B1B8F578 3DF7434B	XXXX
		2C	6632						0320	8A66A557 86499ABE 7BAB59	
27	44	2d	5768	30	02	8d	20	63	60dd	c42b87f4 6fc048d4 2498b44b	3d9c
		2c	6632						0320	5e34f083 e93e6af1 617631	
27	44	2d	5768	30	02	8d	20	8e	11de	188851bd c4b72dd3 c2954a34	494e
		2c	6632						0320	1be369e9 089b4eb3 858169	

#### Encrypted long telegrams:

L	С	M	Α	Ver	Med	CI	CC	ACC	AES	Encrypted payload		CRC	
									CTR				16
2D	44	2D	5768	30	02	8D	20	64	61DD	38931d14	b405536e	0250592f	0e7d
		2C	6632						0320	8b908138	d58602ec	a676ff79	
										e0caf0b1 4d			

#### 1.1.4 Decryption

- The encrypted wireless m-bus on OmniPower uses AES-128 Mode CTR.
- See EN 13757-4:2019, p. 54, as ELL (Ext. Link-Layer) with ECN = 001 => AES-CTR.
- A decryption prefix (initial counter block) is built from some of the fields.
- See table 54 on p. 55 of EN 13757-4:2019.

It can be packed using the format <*HIBBBIB*.

М	Α	Ver	Med	CC	AES CTR	FN	BC
2D2C	57686632	30	02	20	21870320	0000	00

Prefix: M, ..., AES CTR. Counter: FN, BC FN: frame number (frame # sent by meter within same session number, in case of multi-frame transmissions). BC: Block counter (encryption block number, counts up for each 16 byte block decrypted within the telegram).

#### 1.1.5 Decrypted payload examples

The interpretation of the fields in the OmniPower are

Field	Kamstrup	Data fmt	Value type	VIF/E meaning	DIF
	name	(DIF)	(VIF/E)		VIF/E
Data	A+	32-bit uint	Energy, 10 <sup>1</sup> Wh	Consumption from grid, accum.	04 04
1					
Data	A-	32-bit uint	Energy, 10 <sup>1</sup> Wh	Production to grid, accum.	04 84 3C
2					
Data	P+	32-bit uint	Power, 10^0 W	Consumption from grid, instan-	04 2B
3				tan.	
Data	P-	32-bit uint	Power, 10^0 W	Production to grid, instantan.	04 AB 3C
4					

Transport layer control information fields (TPL-CI), ref. EN 13757-7:2018, p. 17, introduce Application Layer (APL) as: - 0x78 with full frames (Response from device, full M-Bus frame) - 0x79 with compact frames (Response from device, M-Bus compact frame)

#### **Decrypted short telegram**

CRC16	TPL-CI	Data fmt. sign.	CRC16 data	Data 1	Data 2	Data 3	Data 4
1170	79	138C	4491	CE000000	00000000	03000000	00000000

Measurement data starts at byte 7, and can easily be extracted using < IIII little-endian format.

In this example, 206 10<sup>1</sup> Wh (2.06 kWh) have been consumed, and the current power draw is 3 10<sup>0</sup> W (0.003 kW).

#### **Decrypted long telegram**

In this kind of telegram, the DRHs are included.

CRC16	TPL-	DIF/VIF	Data 1	DIF/VIF/VIFE	Data 2	DIF/VIF	Data 3	DIF/VIF	Data 4
	CI	1		2		3		4	
9831	78	04 04	D7000000	04 84 3C	00000000	04 2B	03000000	04 AB	00000000
								3C	

Extraction is slightly more complex, requiring either a longer parsing pattern or perhaps a regex.

In this example, 215 10<sup>1</sup> Wh (2.15 kWh) have been consumed, and the current power draw is 3 10<sup>0</sup> W (0.003 kW).

## 1.2 The C1 Telegram class

```
class meter.OmniPower.ClTelegram(telegram: bytes)
```

Implements capture of data fields for a C1 telegram from OmniPower

```
decrypt_using (meter: meter.OmniPower.OmniPower) → bool
```

Decrypts a telegram using the key from the specified meter. Updates the decrypted field of self. Requires instantiated OmniPower meter with valid AES-key.

#### 1.3 The OmniPower class

```
class meter.OmniPower.OmniPower (name: str = 'Kamstrup OmniPower one-phase', meter_id: str = '32666857', manufacturer_id: str = '2C2D', medium: str = '02', version: str = '30', aes_key: str = '9A25139E3244CC2E391A8EF6B915B697')
```

Implementation of our OmniPower single-phase meter Passed values are hex encoded as string, e.g. '2C2D' for value 0x2C2D.

add\_measurement\_to\_log (measurement: meter.MeterMeasurement.MeterMeasurement) → None Pushes a new measurement to the tail end of the log

**decrypt** (*telegram*: meter.OmniPower.C1Telegram) → bytes

#### Decrypt a telegram. Requires:

- the prefix from the telegram (telegram.prefix), and
- the encryption key from the meter.

Decrypts the data stored telegram.encrypted

```
{\tt dump\_log\_to\_json}\:(\:)\:\to str
```

Returns a JSON object of all measurement frames in log, with an incremented number for each observation

ter.MeterMeasurement.MeterMeasurement
Requires that the telegram is already decrypted, otherwise returns empty measurement

```
is this my (telegram: meter.OmniPower.C1Telegram) → bool
```

Check whether a given telegram is from this meter by comparing meter setting to telegram

```
process_telegram (telegram: meter.OmniPower.C1Telegram) → bool
```

Does entire processing chain for a telegram, including adding to log

```
classmethod unpack_long_telegram_data (data: bytes) → Tuple[int, ...]
    Long C1 telegrams contain DIF/VIF information and field data values

classmethod unpack_short_telegram_data (data: bytes) → Tuple[int, ...]
    Short C1 telegrams only contain field data values, no information about DIF/VIF
```

Kamstrup OmniPower wm-bus metering, Release development							

#### IMPLEMENTATION OF GENERIC MEASUREMENTS

## 2.1 Generic class for measurements and measurement frames

```
platform Python 3.5.10 on Linux, OS X
synopsis This module implements classes for generic measurements taken from a meter.
authors Janus Bo Andersen, Jakob Aaboe Vestergaard
date 13 October 2020
```

#### 2.2 The Measurement class

```
class meter.MeterMeasurement.Measurement (value: float, unit: str)
    Single physical measurement. A single measurement of a physical quantity pair, consisting of a value and a
    unit.
```

### 2.3 The MeterMeasurement class

```
class meter.MeterMeasurement.MeterMeasurement(meter_id:
                                                                             str, timestamp:
                                                                                                  date-
                                                                time.datetime)
     A single measurement collection based on one frame from the meter. Will contain multiple measurements of
     physical quantities taken at the same time.
     add_measurement (name: str, measurement: meter.MeterMeasurement.Measurement) → None
          Store a new measurement in the collection.
     as dict() \rightarrow dict
          Serializes and dumps the Measurement frame as a dict. Make an object similar to {
               "Meter ID: ": "3232323", "Timestamp:": "2020-10-13T17:36:53", "Measurements": {
                   "A+": { "unit": "kWh", "value": 7
                   }, "A-": {
                     "unit": "kWh", "value": 8
                   }, "P+": {
                     "unit": "kW", "value": 9
                   }, "P-": {
```

```
"unit": "kW", "value": 10 } \} \} \\ \texttt{json\_dump}() \to str \\ Returns a JSON formatted string of all data in frame.}
```
